## 1. INTRODUCTION

PyXRD is a computer model developed in Python for the simulation of 1-dimensional X-ray diffraction patterns for mixed-layer minerals. It has been developed keeping a multi-specimen full profile fitting strategy in mind. It allows for (semi-)quantification of mixed-layer phases by combining several observed XRD patterns and can perform automatic parameter refinements using several aglorithms.

This document provides for a general overview of the theoretical background on which this model is based, an overview of the actual implementation (code-wise). The online version of this manual also contains instructions on how the general user interface (GUI) written in GTK can be used to create and modify models.

For more detailed information we kindly refer to the source documentation and if that is failing, the source code itself.

If any mistakes are discovered in this document please inform me at mathijs.dumon@ugent.be

## 3. INSTALLATION

### 3.1. WINDOWS

As of PyXRD v0.6.2 there are two options for windows users: (i) either manually install all the dependencies and PyXRD or (ii) use a custom installer which will install PyXRD and all of its dependencies for you.

Note that when using the bundled installer, DEAP is not installed. You will still need to follow the instructions in section 3.1.3

### 3.1.1. BUNDLED INSTALLER

Download and run the bundled installer:
https://github.com/mathijs-
dumon/PyXRD/releases/download/v0.6.9/PyXRD-0.6.9-win32-
bundle.exe
For most of the dependencies this does not require input from your side. However, for the Numpy and Scipy libraries there is currently no easy way to completely automate the installation. As a result, you will have to click 'Next' and/or 'Finish' a few times to complete the installation for these libraries.

Note that this is still an experimental feature. If you encounter problems, please report them by e-mail (mathijs.dumon@ugent.be) and continue by following the instructions for manual installation below.

### 3.1.2. MANUAL INSTALL

The installation is a bit lengthy because PyXRD depends on a number of third-party python modules. Work has started to create a unified installer, but for now you'll have to install them manually. These are the dependencies (more recent versions should also work, except for python which needs to be version 2.7):

- Python: http://www.python.org/ftp/python/2.7.8/python2.7.8.msi
- PyGTK:
http://ftp.gnome.org/pub/GNOME/binaries/win32/pygtk/2.24 /pygtk-all-in-one-2.24.2.win32-py2.7.msi
- Numpy:
http://sourceforge.net/projects/numpy/files/NumPy/1.7.0/nu mpy-1.7.0-win32-superpack-python2.7.exe/download
- Scipy:http://sourceforge.net/projects/scipy/files/scipy/0.14.0/ scipy-0.14.0-win32-superpack-python2.7.exe/download
- Matplotlib:
https://downloads.sourceforge.net/project/matplotlib/matplo tlib/matplotlib-1.2.1/matplotlib-1.2.1.win32-py2.7.exe
- Pyparsing:
http://sourceforge.net/projects/pyparsing/files/pyparsing/pyp arsing-2.0.3/pyparsing-2.0.3.win32-py2.7.exe/download
- Setuptools: https://bootstrap.pypa.io/ez_setup.py

1. Download the script somewhere you can find it (e.g. the desktop)
2. Open a command line as administrator
(Start button $\rightarrow$ Search $\rightarrow$ enter 'cmd.exe' $\rightarrow$ right-click the command line icon and select 'Run as adiministrator')
3. Enter the following command (replace the path to ez_setup to where you have downloaded it):
C: \Python27\python.exe
c:\users\myusername\Desktop\ez_setup.py
This assumes you have installed python in C:\Python27
(the default location), if not change the command accordingly.
Finally download and install PyXRD:
https://github.com/mathijs-
dumon/PyXRD/releases/download/v0.6.9/PyXRD-0.6.9.win32.exe

### 3.1.3. INSTALLATION OF DEAP

You can optionally install DEAP which will provide evolutionary refinement algorithms:

1. Open a command line as administrator (Start button $\rightarrow$ Search $\rightarrow$ enter 'cmd.exe' $\rightarrow$ right-click the command line icon and select 'Run as adiministrator')
2. Enter the following command:

C:\Python27\Scripts\easy_install.exe deap

### 3.2. LINUX

Installation on linux should be straightforward, first install Python 2.7 and PyGTK:

- Debian/Ubuntu/...
sudo apt-get install python python-gtk2
- Fedora/Red Hat/... (untested)
sudo yum install python python-gtk
- OpenSuSE (untested)
sudo yum install python python-gtk
Then you can choose to either install the dependencies from your package manager repositories or using pip or easy_install. Usually it is preferable to use the binaries from the package manager as you will not need to install them by hand. The dependencies are:
- Numpy >= 1.7.0
- Scipy $>=0.14 .0$
- Matplotlib >= 1.2.1
- Pyparsing >= 2.0.4
- Setuptools

And the corresponding commands would be:

- Debian/Ubuntu/... sudo apt-get install python-numpy python-scipy python-matplotlib
- Fedora/Red Hat/... (untested)
sudo yum install python python-gtk python-numpy python-scipy pythonmatplotlib
- OpenSuSE (untested)
sudo yum install python python-gtk python-numpy python-scipy pythonmatplotlib

Once this has been completed, open a terminal and enter these commands:

## sudo easy_install pip

pip install --user 'pyxrd>=0.6.9'
This will install everything under your '~/.local' folder. To run PyXRD type in the following:
~/.local/bin/PyXRD
or make a shortcut to this command.

## 4. THEORETICAL BACKGROUND

### 4.1. GENERAL MATHEMATICAL FORMALISM

The mathematical formalisms on which PyXRD is based is described in a number of articles and books published over the years. Relevant references can be found at the end of this section. Below an overview will be given of the different parts of the general matrix formalism.

The general matrix formalism (described in detail in Drits \& Tchoubar (1990)) allows to calculate the diffraction pattern for a single mixedlayer phase A as:
$\mathrm{I}_{\mathrm{A}}(\mathrm{s}) \propto \frac{\mathrm{wf}_{\mathrm{A}}}{\overline{\rho_{\mathrm{A}}} \cdot \overline{\mathrm{V}}_{\mathrm{A}}} \cdot \Xi \cdot \sum_{\mathrm{n}=1}^{\mathrm{M}} \alpha(\mathrm{n}) \int_{\phi} \Re \operatorname{Tr}\{[\mathrm{F}] \cdot[\mathrm{W}] \cdot[\mathrm{R}]\} \cdot \overline{\mathrm{T}_{\mathrm{n}}(\mathrm{U})} \cdot \overline{\mathrm{p}}(\phi) \cdot \mathrm{d} \phi \quad$ (eq. box 1)
in which:

particles (also known as the powder ring distribution factor), (see chapter 20)

| $\alpha(\mathrm{n})$ | is the fraction of crystallites with a coherent <br> scattering domain size (CSDS) of $n$ layers (see <br> chapter 19) |
| :--- | :--- |
| $[F]$ | the structure factor matrix (see chapter 13 ); |
| $[W]$ | the weight fraction matrix (see chapter 25 ); |
| $[R]$ | is defined as $[R]=[I]+2 \cdot \sum_{m=1}^{M-1} \frac{M-m}{M} \cdot[Q]^{m}$ in | which [I] is the identity matrix, M the number of layers in the considered CSDS and [Q] is the nearest neighbour phase difference matrix (see chapter 16)

$\overline{\mathrm{T}_{\mathrm{n}}}(\mathrm{U}) \quad$ is the mean area of the coherent scatter domain with $n$ layers, which can be approximated by n . $\overline{\mathrm{c}}=\mathrm{n} \cdot \sum_{\mathrm{G}} \quad \mathrm{c}_{\mathrm{g}} \cdot \mathrm{W}_{\mathrm{g}}$ in which $\overline{\mathrm{c}}$ is the average d spacing and $c_{g}$ is the $d$-spacing of g-th component
$\overline{\mathrm{p}}(\phi) \quad$ is the (normalized) probability of finding a layer deviating $\phi$ radians from perfect orientation

In the following sections, the calculation of each of the matrices and functions is explained in more detail.

### 4.2. LENGTH OF THE RECIPROCAL VECTOR: $S$

The length of the reciprocal vector (commonly denoted as $\overrightarrow{\mathbf{s}}$ ) can be expressed as:
$|\vec{s}|=s=\frac{2 \cdot \sin \theta}{\lambda}$ (eq. box 2)
in which:

$$
\begin{array}{ll}
\theta & \text { the angle of the incident X-ray bundle } \\
\lambda & \text { the wavelength of the X-ray waves }
\end{array}
$$

It relates with Bragg's formula like this:

$$
\begin{gather*}
2 \cdot d \cdot \sin (\theta)=n \cdot \lambda \\
\frac{2 \cdot \sin (\theta)}{\lambda}=\frac{n}{d}=s \tag{eq.box3}
\end{gather*}
$$

### 4.3. CALCULATION OF THE STRUCTURE FACTOR MATRIX F

### 4.3.1. GENERAL

The actual size of the $F$ and $Q$ matrices depends on the Reichweite of the model. Therefore this section is split in two parts: first the setup of the structure factor matrix for R0 and R1 models is explained, and then it is explained how that matrix can be scaled to match the higher Reichweite models. The basis for this elaboration is based for the larger part on principles and examples found in Drits \& Tchoubar (1990).

## LAYOUT FOR R0 AND R1 MODELS

The structure factor matrix $F$ then has the following definition:

$$
\mathrm{F}=\left[\begin{array}{rrrr}
\mathrm{F}_{1} \mathrm{~F}_{1}^{*} & \mathrm{~F}_{2} \mathrm{~F}_{1}^{*} & \ldots & \mathrm{~F}_{\mathrm{G}} \mathrm{~F}_{1}^{*} \\
\mathrm{~F}_{1} \mathrm{~F}_{2}^{*} & \mathrm{~F}_{2} \mathrm{~F}_{2}^{*} & \ldots & \mathrm{~F}_{\mathrm{G}} \mathrm{~F}_{2}^{*} \\
\ldots & \ldots & \ldots & \ldots \\
\mathrm{~F}_{1} \mathrm{~F}_{\mathrm{G}}^{*} & \mathrm{~F}_{2} \mathrm{~F}_{\mathrm{G}}^{*} & \ldots & \mathrm{~F}_{\mathrm{G}} \mathrm{~F}_{\mathrm{G}}^{*}
\end{array}\right.
$$

in which:

| $\mathrm{F}_{\mathrm{g}}$ | the structure factor for the g-th component (see |
| :--- | :--- |
| $\mathrm{F}_{\mathrm{g}}^{*}$ | 14) |
|  | its complex conjugate |

The complete structure factor matrix $F$ can be constructed from simpler matrices. First we create a 1D matrix Fa containing the structure factors for each component:
$\mathrm{F}_{\mathrm{a}}=\left[\begin{array}{llll}\mathrm{F}_{1} & \mathrm{~F}_{2} & \ldots & \mathrm{~F}_{\mathrm{G}}\end{array}\right]$
(eq. box 5)
After this we create another 1D matrix $F_{b}$ which is the transposeconjugated form of matrix $F_{a}$ :
$\mathrm{F}_{\mathrm{b}}=\mathrm{F}_{\mathrm{a}}^{* \mathrm{~T}}=\begin{gathered}\mathrm{F}_{1}^{*} \\ {\left[\begin{array}{c}\mathrm{F}_{2}^{*} \\ \ldots \\ \ldots \\ \mathrm{~F}_{\mathrm{G}}^{*}\end{array}\right]}\end{gathered}$

The structure factor matrix $F$ can then be constructed by multiplying matrices $F_{b}$ with $F_{a}$ :
(eq. box 7)

## SCALING FOR HIGHER REICHWEITE MODELS

For models with $R>1$ the matrix needs to be of size GR. To accomplish this, each pair of structure factors is replaced with a sub-matrix of size GR-1 of the form:

$$
\mathrm{F}_{\mathrm{ij}}=\left[\begin{array}{cccc}
\mathrm{F}_{\mathrm{i}} \mathrm{~F}_{\mathrm{j}}^{*} & \mathrm{~F}_{\mathrm{i}} \mathrm{~F}_{\mathrm{j}}^{*} & \ldots & \mathrm{~F}_{\mathrm{i}} \mathrm{~F}_{\mathrm{i}}^{*} \\
\mathrm{~F}_{\mathrm{j}}^{*} & \mathrm{~F}_{\mathrm{i}}^{*} \mathrm{~F}_{\mathrm{j}}^{*} & \ldots & \mathrm{~F}_{\mathrm{i}} \mathrm{~F}_{\mathrm{j}}^{*} \tag{eq.box8}
\end{array}\right]
$$

With other words, each pair of structure factors is replaced with a 'sub-matrix' of size GR-1 in which each element is a duplicate of the replaced pair of structure factors.

### 4.3.2. STRUCTURE FACTOR FN FOR A COMPONENT

The structure factor characterizing the X-ray scattering by an infinite, three-dimensional atomic motif can, in general, be written as:
$\mathrm{F}_{\mathrm{hkl}}(\mathrm{s})=\sum_{\mathrm{m}} \mathrm{f}_{\mathrm{m}}(\mathrm{s}) \cdot \exp \left(2 \cdot \pi \cdot \mathrm{i} \cdot\left(\frac{\mathrm{h} \cdot \mathrm{x}_{\mathrm{m}}}{\mathrm{a}}+\frac{\mathrm{k} \cdot \mathrm{y}_{\mathrm{m}}}{\mathrm{b}}+\frac{\mathrm{l} \cdot \mathrm{z}_{\mathrm{m}}}{\mathrm{c}}\right)\right)$
in which:

| m | the number of atoms in the motif of the component |
| :---: | :---: |
| $f_{m}(\mathrm{~s})$ | the scattering factor for the m-th atom |
| $\mathbf{x}_{\mathrm{m}}, \mathbf{y m}_{\mathrm{m}}, \mathbf{z}_{\mathrm{m}}$ | the position of the m -th atom along the $\mathrm{X}, \mathrm{Y}$ and Z axes of the motif (in nm ) |
| h, k, I | the miller indices of the reflection being calculated |
| $a, b, c$ | unit cell dimensions along the $X, Y$ and $Z$ axes of the motif (in nm) |

$$
\begin{aligned}
& \mathrm{F}=\mathrm{F}_{\mathrm{b}} \cdot \mathrm{~F}_{\mathrm{a}}=\mathrm{F}_{\mathrm{a}}^{* \mathrm{~T}} \cdot \mathrm{~F}_{\mathrm{a}} \\
& \mathrm{~F}_{1}^{*} \\
& \mathrm{~F}=\left[{ }^{\mathrm{F}_{2}^{*}}\right] \cdot\left[\begin{array}{llll}
\mathrm{F}_{1} & \mathrm{~F}_{2} & \ldots & \mathrm{~F}_{\mathrm{G}}
\end{array}\right] \\
& \mathrm{F}_{\mathrm{G}}^{*} \\
& \mathrm{~F}_{1} \mathrm{~F}_{1}^{*} \quad \mathrm{~F}_{2} \mathrm{~F}_{1}^{*} \quad \ldots \quad \mathrm{~F}_{\mathrm{G}} \mathrm{~F}_{1}^{*} \\
& F=\left[\begin{array}{cccc}
\mathrm{F}_{1} \mathrm{~F}_{2}^{*} & \mathrm{~F}_{2} \mathrm{~F}_{2}^{*} & \ldots & \mathrm{~F}_{\mathrm{G}} \mathrm{~F}_{2}^{*} \\
\ldots & \ldots & \ldots & \ldots
\end{array}\right] \\
& \begin{array}{llll}
\mathrm{F}_{1} \mathrm{~F}_{\mathrm{G}}^{*} & \mathrm{~F}_{2} \mathrm{~F}_{\mathrm{G}}^{*} & \ldots & \mathrm{~F}_{\mathrm{G}} \mathrm{~F}_{\mathrm{G}}^{*}
\end{array}
\end{aligned}
$$ 12)

i the unreal number $(=\sqrt{(-1)})$
However, since we are only interested in 00l-reflections, the $h$ and $k$ terms can be dropped and the structure factor for this 1-dimensional atomic motif can be written as:
$\mathrm{F}_{\mathrm{n}}=\sum_{\mathrm{m}} \mathrm{f}_{\mathrm{m}}(\mathrm{s}) \cdot \exp \left(2 \cdot \pi \cdot \mathrm{i} \cdot \frac{1 \cdot \mathrm{z}_{\mathrm{m}}}{\mathrm{c}}\right)$
According to Bragg's law, we can write (also see section 12):
$\frac{2 \cdot \sin (\theta)}{\lambda}=\frac{n}{c}=s$
(eq. box 11)
Combining the above two relations and setting $n=1$ and $I=1$, we can write:
$\mathrm{F}_{\mathrm{n}}=\sum_{\mathrm{m}} \mathrm{f}_{\mathrm{m}}(\mathrm{s}) \cdot \exp \left(2 \cdot \pi \cdot \mathrm{i} \cdot \mathrm{z}_{\mathrm{m}} \cdot \mathrm{s}\right)$
(eq. box 12)
in which:

| $\mathbf{m}$ | the number of atoms in the motif of the <br> component |
| :--- | :--- |
| $\boldsymbol{f}_{\boldsymbol{m}}(\mathbf{s})$ | the scattering factor for the m -th atom (see <br> chapter 16$)$ |
| $\mathbf{z}_{\mathrm{m}}$ | the position of the m-th atom along the Z axis of <br> the motif |
| $\mathbf{s}$ | the length of the reciprocal vector (see chapter <br> $12)$ |
| $\mathbf{i}$ | the unreal number $(=\sqrt{(-1))}$ |

The complex conjugate of the structure factor is (see chapter 13):
$\mathrm{F}_{\mathrm{n}}^{*}=\sum_{\mathrm{m}} \mathrm{f}_{\mathrm{m}}(\mathrm{s}) \cdot \exp \left(-2 \cdot \pi \cdot \mathrm{i} \cdot \mathrm{z}_{\mathrm{m}} \cdot \mathrm{s}\right)$
(eq. box 13)
This exponential relation can be transformed using Euler's formula into the sine and cosine form:
$\mathrm{F}_{\mathrm{n}}=\sum_{\mathrm{m}} \mathrm{f}_{\mathrm{m}}(\mathrm{s}) \cdot\left[\cos \left(2 \cdot \pi \cdot \mathrm{i} \cdot \mathrm{z}_{\mathrm{m}} \cdot \mathrm{s}\right)+\mathrm{i} \cdot \sin \left(2 \cdot \pi \cdot \mathrm{i} \cdot \mathrm{z}_{\mathrm{m}} \cdot \mathrm{s}\right)\right]$
(eq. box 14)
The complex conjugate of this formula can then be written as:
$\mathrm{F}_{\mathrm{n}}^{*}=\sum_{\mathrm{m}} \mathrm{f}_{\mathrm{m}}(\mathrm{s}) \cdot\left[\cos \left(2 \cdot \pi \cdot \mathrm{i} \cdot \mathrm{z}_{\mathrm{m}} \cdot \mathrm{s}\right)-\mathrm{i} \cdot \sin \left(2 \cdot \pi \cdot \mathrm{i} \cdot \mathrm{z}_{\mathrm{m}} \cdot \mathrm{s}\right)\right] \quad($ eq. box 15)

### 4.3.3. ATOMIC SCATTERING FACTOR FOR A SINGLE ATOM: $^{m}$

The atomic scattering factor for a single atom is calculated using the Cromer-Mann coëfficiënts as published in Waasmaier and Kirfel (1995). The Debye constants are set to:

| $\mathbf{0}$ | for neutral atoms |
| :--- | :--- |
| $\mathbf{2}$ | for anions |
| $\mathbf{1 . 5}$ | for cations |

The atomic scattering factor is calculated as follows:
$\mathrm{f}_{\mathrm{m}}(\mathrm{s})=\mathrm{P}_{\mathrm{m}} \cdot\left[\mathrm{c}+\sum_{\mathrm{i}=1}^{5}\left(\mathrm{a}_{\mathrm{i}} \cdot \exp \left(-\mathrm{b}_{\mathrm{i}} \cdot \frac{\mathrm{s}^{2}}{2 \cdot 10}\right)\right)\right] * \exp \left(-\mathrm{B}_{\mathrm{m}} * \mathrm{~s}^{2}\right) \quad$ (eq. box 16) in which:
$\mathbf{P}_{\mathrm{m}} \quad$ the number of atoms per unit cell at this $z$ location (can be > 1 due to the projection on the Z-axis)
c constant of the exponential approximation of the scattering factor
$a_{i}$ the $i$-th a factor of the exponential approximation of the scattering factor
$\mathbf{b}_{\mathbf{i}}$ the i -th b factor of the exponential approximation of the scattering factor
the length of the reciprocal vector (see chapter 12)
$\mathbf{B}_{\mathrm{m}} \quad$ the Debye constant for the m -th atom
The factor 10 in the exponential part of the summation is there to convert the units of the reciprocal vector s from nanometer to Ångstrom (factor 10).

### 4.4. CALCULATION OF THE PHASE FACTOR MATRIX Q

### 4.4.1. GENERAL

As explained in section 13, the actual size of the $F$ and $Q$ matrices depends on the Reichweite of the model. This section is also split in two parts: first the setup of the phase factor matrix for RO and R1 models is explained, and then it is explained how that matrix can be scaled to match the higher Reichweite models.

## LAYOUT FOR R0 AND R1 MODELS

The phase factor matrix Q is the Hadamard product (element-wise product, not the regular matrix multiplication) of two other matrixes:

$$
\mathrm{Q}=[\phi] \circ \mathrm{P}
$$

of which the first term can be defined as follows:

$$
[\phi]=\left[\begin{array}{cccc}
\phi_{11} & \phi_{12} & \ldots & \phi_{1 \mathrm{n}} \\
\phi_{21} & \phi_{22} & \ldots & \phi_{2 \mathrm{n}} \\
\ldots & \ldots & \ldots & \ldots
\end{array}\right]
$$

in which:
بij the phase difference between the i-th and j-th component in the mixed-layer phase

The matrix $P$ contains the probability parameters. Its calculation is detailed in chapter 25 for different values of $R$ and will not be discussed in further detail here.

## SCALING FOR HIGHER REICHWEITE MODELS

For models with $R>1$ the [ $\phi$ ] matrix needs to be of size GR. To accomplish this, each phase difference $\left[\phi_{\mathrm{ij}}\right]$ is replaced with a submatrix of size GR-1 of the form:
$\left[\phi_{\mathrm{ij}}\right]=\left[\begin{array}{cccc}\phi_{\mathrm{ij}} & \phi_{\mathrm{ij}} & \ldots & \phi_{\mathrm{ij}} \\ \phi_{\mathrm{ij}} & \phi_{\mathrm{ij}} & \ldots & \phi_{\mathrm{ij}} \\ \ldots & \ldots & \ldots & \ldots \\ \phi_{\mathrm{ij}} & \phi_{\mathrm{ij}} & \ldots & \phi_{\mathrm{ij}}\end{array}\right]$
(eq. box 19)

With other words, each phase difference is replaced with a sub-matrix of size GR-1 in which each element is a duplicate of the replaced phase difference.

### 4.4.2. PHASE DIFFERENCE BETWEEN THE I-TH AND J-TH

## COMPONENTS $\Phi_{4}$

The phase difference depends on the distance between the components. If we define the $i$-th component as the one preceeding the $j$-th component, the phase difference depends on the basal spacing of that $i$-th component (and not of the $j$-th component):
$\varphi=\mathrm{e}^{2 \cdot \pi \cdot \mathrm{~s} \cdot \mathrm{~d}_{001} \cdot \mathrm{i}} \cdot \mathrm{e}^{-2 \cdot\left(\pi \cdot \mathrm{~s} \cdot \delta_{001}\right)^{2}}=\mathrm{e}^{2 \cdot \mathrm{\pi} \cdot \mathrm{~s} \cdot\left(\mathrm{~d}_{001} \cdot \mathrm{i}-\pi \cdot \mathrm{s} \cdot \delta_{001}^{2}\right)}$
(eq. box 20)
in which:

| s | the length of the reciprocal vector (see chapter |
| :--- | :--- |
| i | 12) |
| $\mathrm{d}_{001}$ | the unreal number $(=\sqrt{(-1)})$ |
| $\delta_{001}$ | the basal spacing of the i-th component (nm) |
|  | the variation in the basal spacing of the i-th |
| component $(\mathrm{nm})$ |  |

In Plançon (2002) an equation can be found on how to insert variable d-spacings. A similar formulation can also be found in Drits \& Tchoubar (1990, page 89), albeit with different constants. The latter has been implemented in PyXRD, as it matched with the output from Sybilla. It assumes a Gaussian distribution of the $d$-spacing around the default $d$ spacing.
$F_{\mathrm{n}}^{\prime}=\sum_{\mathrm{m}} \mathrm{f}_{\mathrm{m}}(\mathrm{s}) \cdot \mathrm{e}^{2 \cdot \pi \cdot \mathrm{i} \cdot \mathrm{z}_{\mathrm{m}} \cdot \mathrm{s}} \cdot \mathrm{e}^{-2 \cdot \pi^{2} \cdot \delta_{001}^{2} \cdot \mathrm{~s}^{2}}$
(eq. box 21)
in which:

| $\mathbf{m}$ | the number of atoms in the motif of the <br> component <br> the scattering factor for the m-th atom (see <br> chapter 16) |
| :--- | :--- |
| $\boldsymbol{f}_{m}(\mathbf{s})$ | the position of the $m$-th atom along the $Z$ axis of <br> the motif |
| $\mathbf{z m}_{\mathrm{m}}$ | the length of the reciprocal vector (see chapter <br> 12) |
| $\delta_{001}^{2}$ | the variable d-spacing standard deviation <br> (assuming a Gaussian distribution) |
| $\mathbf{i}$ | the unreal number $(=\sqrt{(-1)})$ |

### 4.5. CALCULATION OF THE COHERENT SCATTERING DOMAIN SIZE

## (CSDS) DISTRIBUTION FUNCTION A

Several functions have been proposed in the past. Their definitions are detailed below. Currently in the model only a generic log-normal distribution and the log-normal distribution as proposed in Drits et al. (1997) are implemented.

In general, the arithmetic mean CSDS can be calculated from whatever CSDS distribution function is used by:
$\overline{\mathrm{N}}=\sum_{\mathrm{n}=1}^{\mathrm{N}_{\text {max }}} \mathrm{n} \cdot \alpha(\mathrm{n})$
(eq. box 22)

### 4.5.1. ERGUN MODEL (NOT IMPLEMENTED)

One of the first CSDS distributions proposed is that of Ergun (1970):
$\alpha(\mathrm{n})=\exp \left(\frac{2-\mathrm{N}}{\delta}\right)$
(eq. box 23)
in which:
n the CSDS value of interest
$\delta \quad$ the mean defect-free number of layers

However, this simple model is not used often anymore and has been replaced by a log-normal CSDS distribution, as detailed in Drits et al. (1997).

### 4.5.2. LOG-NORMAL MODELS

The log-normal models assume a log-normal distribution of CSDS values.
The basic definition is:
$\alpha(\mathrm{n})=\sqrt{\frac{2 \cdot \pi}{\mathrm{~B}^{2} \cdot \mathrm{n}^{2}}} \cdot \exp \left(\frac{-(\log (\mathrm{n})-(\mathrm{A}))^{2}}{2 \cdot \mathrm{~B}^{2}}\right)$
in which:
$n \quad$ the CSDS value of interest
A the mean of the probability density function, defined as: $A=a_{1} \cdot \log (\overline{\mathrm{~N}})+\mathrm{a}_{2}$
in which a1 and a2 are empirical constants and N is the average CSDS.
$B^{2}$ the variance of the probability density function, defined as:

$$
\mathrm{B}^{2}=\mathrm{b}_{1} \cdot \log (\overline{\mathrm{~N}})+\mathrm{b}_{2}
$$

in which b1 and b2 are empirical constants and $N$ is the average CSDS.
This model is implemented in PyXRD, together with a model which has pre-set values for the $a_{1}, a_{2}, b_{1}$ and $b_{2}$ parameters (according to Drits et al. (1997)):

| $\mathrm{a}_{1}$ | $=0.9485$ |
| :--- | :--- |
| $\mathrm{a}_{2}$ | $=0.0170$ |
| $\mathrm{~b}_{1}$ | $=0.1032$ |
| $\mathrm{~b}_{2}$ | $=0.0034$ |

### 4.6. PREFERRED ORIENTATION

A correction for preferred orientation of phases should be applied. The basis for these corrections was laid by Reynolds (1986) and the importance of these corrections has recently been reiterated upon by Dohrmann et al. (2009). The effect of preferred orientation (calculated as $\psi$ ) is usually grouped with the Lorentz-Polarisation factor into $\Xi$ :

$$
\begin{gathered}
S=\sqrt{\frac{\mathrm{S}_{1}^{2}+\mathrm{S}_{2}^{2}}{4}} \\
\mathrm{Q}=\frac{\mathrm{S}}{\sqrt{8} \cdot \sin (\theta) \cdot \sigma^{*}} \\
\psi=\operatorname{erf} \frac{(\mathrm{Q}) \cdot \sqrt{2 \cdot \pi}}{2 \cdot \sigma^{*} \cdot \mathrm{~S}}-2 \cdot \sin (\theta) \cdot\left(\frac{1-\mathrm{e}^{-\mathrm{Q}^{2}}}{\mathrm{~S}^{2}}\right) \\
\Xi=\frac{1+\cos ^{2}(2 \theta)}{\sin (2 \theta)} \cdot \psi
\end{gathered}
$$

(eq. box 25)

We also need to describe the distribution of the orientation of the particles in our sample. If our sample is well-oriented, we can assume a Gaussian distribution with a standard deviation $\sigma^{*}$ (Dohrmann et al., 2009) so that the distribution fuction $\overline{\mathrm{p}}(\phi)$ becomes:
$\overline{\mathrm{p}}(\phi)=\frac{1}{\sigma^{*} \cdot \sqrt{2 \cdot \pi}} \cdot \mathrm{e}^{\frac{-\phi^{2}}{2 \cdot\left(\sigma^{*}\right)^{2}}}$ (eq. box 26)

In the general equation, this function needs to be integrated over the entire domain of $\phi$ leading to:
$\int_{\phi_{\text {min }}}^{\phi_{\text {max }}} \overline{\mathrm{p}}(\phi) \mathrm{d} \phi=\frac{1}{2} \cdot\left[1+\operatorname{erf}\left(\frac{\phi_{\text {max }}}{\sigma^{*} \cdot \sqrt{2}}\right)-\operatorname{erf}\left(\frac{\phi_{\text {min }}}{\sigma^{*} \cdot \sqrt{2}}\right)\right]$

Since for an oriented sample $\phi_{\min }=0$ and $\phi_{\max } \gg \sigma^{*}$, we can approximate this:
$\int_{\phi_{\min }}^{\phi_{\max }} \overline{\mathrm{p}}(\phi) \mathrm{d} \phi \simeq \frac{1}{2} \cdot[1+1-0]=1$
(eq. box 28)
As a result, for an oriented sample, equation 1 becomes:
$\mathrm{I}_{\mathrm{A}}(\mathrm{s}) \propto \frac{\mathrm{wf}_{\mathrm{A}}}{\overline{\overline{\mathrm{A}}_{\mathrm{A}}} \cdot \overline{\mathrm{V}_{\mathrm{A}}}}{ }^{2} \cdot \Xi \cdot \sum_{\mathrm{n}=1}^{\mathrm{M}} \alpha(\mathrm{n}) \cdot \mathfrak{R} \operatorname{Tr}\{[\mathrm{F}] \cdot[\mathrm{W}] \cdot[\mathrm{R}]\} \cdot \overline{\mathrm{T}_{\mathrm{n}}(\mathrm{U})} \quad$ (eq. box 29)

### 4.7. OPTIMIZATION OF THE FORMALISM

The equation 29 can be further optimized to allow for a more efficient calculation process.

If we drop in the relations given for $\overline{T_{n}}(U)$ and $[R]$ detailed in chapter 11, we arrive at:

$$
\begin{aligned}
& \mathrm{I}_{\mathrm{A}}(\mathrm{~s}) \propto \frac{\mathrm{wf}_{\mathrm{A}}}{\overline{{\overline{\rho_{A}} \cdot}_{\mathrm{V}_{\mathrm{A}}}{ }^{2}} \cdot \Xi} \\
& \cdot \sum_{\mathrm{n}=1}^{\mathrm{M}} \alpha(\mathrm{n}) \cdot \mathrm{n} \cdot \overline{\mathrm{c}} \cdot \mathfrak{R} \operatorname{Tr}\left\{[\mathrm{~F}] \cdot[\mathrm{W}] \cdot\left[[\mathrm{I}]+2 \cdot \sum_{\mathrm{m}=1}^{\mathrm{n}-1} \frac{\mathrm{n}-\mathrm{m}}{\mathrm{n}} \cdot[\mathrm{Q}]^{\mathrm{m}}\right]\right\} \\
& \quad \text { (eq. box } 30 \text { ) }
\end{aligned}
$$

Since $\alpha(\mathrm{n})$ and n are real numbers we can bring them inside the $\mathfrak{R T r}$ operators, and since $\bar{c}$ is independent of $n$ we can take it out of the outermost summation, leading to:
$\mathrm{I}_{\mathrm{A}}(\mathrm{s}) \propto \frac{\overline{\mathrm{c}} \cdot \mathrm{wf}_{\mathrm{A}}}{\overline{\rho_{\mathrm{A}}} \cdot \overline{\mathrm{V}}_{\mathrm{A}}{ }^{2}} \cdot \mathrm{\Xi}$

$$
\cdot \sum_{\mathrm{n}=1}^{\mathrm{M}} \Re \operatorname{Tr}\left\{[\mathrm{~F}] \cdot[\mathrm{W}] \cdot \alpha(\mathrm{n}) \cdot \mathrm{n} \cdot \overline{\mathrm{c}} \cdot\left[[\mathrm{II}]+2 \cdot \sum_{\mathrm{m}=1}^{\mathrm{n}-1} \frac{\mathrm{n}-\mathrm{m}}{\mathrm{n}} \cdot[\mathrm{Q}]^{\mathrm{m}}\right]\right\}
$$

In addition, since [F] and [W] are independent of $n$, we can take them out of the outer summation (together with the $\mathfrak{R T r}$ operators), and re-write this as:

$$
\begin{aligned}
& \mathrm{I}_{\mathrm{A}}(\mathrm{~s}) \propto \frac{\overline{\mathrm{c}} \cdot \mathrm{wf}_{\mathrm{A}}}{{\overline{\rho_{\mathrm{A}}} \cdot{\overline{\mathrm{~V}_{\mathrm{A}}}}^{2}}^{\mathrm{A}}} \mathrm{\Xi} \cdot \mathrm{R} \operatorname{Tr}\left\{[\mathrm{~F}] \cdot[\mathrm{W}] \cdot \sum_{\mathrm{n}=1}^{\mathrm{M}} \alpha(\mathrm{n}) \cdot \mathrm{n} \cdot[[\mathrm{I}]+2\right. \\
&\left.\left.\cdot \sum_{\mathrm{m}=1}^{\mathrm{n}-1} \frac{\mathrm{n}-\mathrm{m}}{\mathrm{n}} \cdot[\mathrm{Q}]^{\mathrm{m}}\right]\right\}
\end{aligned}
$$

(eq. box 32)

At this point we have already reduced calculating $[\mathrm{F}] \cdot[\mathrm{W}] \mathrm{M}$ times to calculating it only once. But we can still improve this a little bit.

We can distribute the $\alpha(\mathrm{n}) \cdot \mathrm{n}$ term over the sum of the identity matrix and the inner summation, which cancels the division by $n$ in there. If we also split this summation of a sum in the sum of two summations, we arrive at:
$\mathrm{I}_{\mathrm{A}}(\mathrm{s}) \propto \frac{\overline{\mathrm{c}} \cdot \mathrm{wf}_{\mathrm{A}}}{\overline{\bar{\rho}_{\mathrm{A}}} \cdot \overline{\mathrm{V}}_{\mathrm{A}}}{ }^{2} \cdot \Xi \cdot \mathfrak{R} \operatorname{Tr}\left\{[\mathrm{~F}] \cdot[\mathrm{W}] \cdot\left[\sum_{\mathrm{n}=1}^{\mathrm{M}} \quad \alpha(\mathrm{n}) \cdot \mathrm{n} \cdot[\mathrm{I}]+2\right.\right.$.
$\left.\left.\sum_{\mathrm{n}=1}^{\mathrm{M}} \sum_{\mathrm{m}=1}^{\mathrm{M}-1} \alpha(\mathrm{n}) \cdot(\mathrm{n}-\mathrm{m}) \cdot[\mathrm{Q}]^{\mathrm{m}}\right]\right\}$
(eq. box 33)

Since the arithmetic mean for the CSDS is defined as $\bar{M}=\sum_{n=1}^{M} \alpha(n) \cdot n$ and $[I]$ is independent of $n$, we can change this to:
$\mathrm{I}_{\mathrm{A}}(\mathrm{s}) \propto \frac{\overline{\mathrm{c}} \cdot \mathrm{wf}_{\mathrm{A}}}{\overline{\rho_{\mathrm{A}}} \cdot \overline{\mathrm{V}_{\mathrm{A}}}} \cdot \mathrm{\Xi} \cdot \mathfrak{R} \operatorname{Tr}\{[\mathrm{~F}] \cdot[\mathrm{W}] \cdot[\overline{\mathrm{M}} \cdot[\mathrm{I}]+$ $\left.\left.2 \cdot \sum_{\mathrm{n}=1}^{\mathrm{M}} \sum_{\mathrm{m}=1}^{\mathrm{M}-1} \alpha(\mathrm{n}) \cdot(\mathrm{n}-\mathrm{m}) \cdot[\mathrm{Q}]^{\mathrm{m}}\right]\right\}$
[s]
(eq. box 34)
The double summation term, indicated in equation 34 as [S], can now be considered separately. When we write this summation in full, we arrive at a sum of $M-1$ summations, of which the first summation will have one term, and the last will have $\mathrm{M}-1$ terms, or:

$$
\begin{gather*}
{[\mathrm{S}]=\sum_{\mathrm{n}=1}^{\mathrm{M}} \sum_{\mathrm{m}=1}^{\mathrm{M}-1} \alpha(\mathrm{n}) \cdot(\mathrm{n}-\mathrm{m}) \cdot[\mathrm{Q}]^{\mathrm{m}}=} \\
\alpha(2) \cdot\left[(2-1) \cdot[\mathrm{Q}]^{1}\right] \\
+\alpha(3) \cdot\left[(3-1) \cdot[\mathrm{Q}]^{1}+(3-2) \cdot[\mathrm{Q}]^{2}\right] \\
+\cdots \\
+\alpha(\mathrm{M}) \cdot\left[(\mathrm{M}-1) \cdot[\mathrm{Q}]^{1}+(\mathrm{M}-2) \cdot[\mathrm{Q}]^{2}+\cdots+(\mathrm{M}-(\mathrm{M}-1)) \cdot[\mathrm{Q}]^{\mathrm{M}-1}\right] \\
(\mathrm{M}-1) \text { terms }
\end{gather*}
$$

box 35)

Since these terms have a lot of $Q^{n}$ matrices in common, summing them in this way is rather time consuming (especially when $Q$ has a high rank). This can be solved by re-grouping these common [Q] ${ }^{\mathrm{n}}$ terms as follows:

$$
\begin{gathered}
{[\mathrm{S}]=\sum_{\mathrm{n}=1}^{\mathrm{M}} \sum_{\mathrm{m}=1}^{\mathrm{M}-1} \alpha(\mathrm{n}) \cdot(\mathrm{n}-\mathrm{m}) \cdot[\mathrm{Q}]^{\mathrm{m}}=} \\
{[\alpha(2) \cdot(2-1)+\alpha(3) \cdot(3-1)+\cdots+\alpha(\mathrm{M}) \cdot(\mathrm{M}-1)] \cdot[\mathrm{Q}]^{1}} \\
+[\alpha(3) \cdot(3-2)+\alpha(4) \cdot(4-2)+\cdots+\alpha(\mathrm{M}) \cdot(\mathrm{M}-2)] \cdot[\mathrm{Q}]^{2} \quad(\text { eq. } . \\
\quad(\mathrm{M}-2) \text { terms } \\
+\cdots \\
+[\alpha(\mathrm{M}) \cdot(\mathrm{M}-(\mathrm{M}-1))] \cdot[\mathrm{Q}]^{\mathrm{M}-1} \\
\quad \begin{array}{c}
1 \text { ter }
\end{array} \\
\text { box 36) }
\end{gathered}
$$

Which can be written as a summation again like this:

$$
[\mathrm{S}]=\sum_{\mathrm{n}=1}^{\mathrm{M}} \sum_{\mathrm{m}=1}^{\mathrm{M}-1} \alpha(\mathrm{n}) \cdot(\mathrm{n}-\mathrm{m}) \cdot[\mathrm{Q}]^{\mathrm{m}}=\sum_{\mathrm{n}=1}^{\mathrm{M}}[\mathrm{Q}]^{\mathrm{n}} \cdot \sum_{\mathrm{m}=\mathrm{n}+1}^{\mathrm{M}} \alpha(\mathrm{~m})
$$

$$
(\mathrm{m}-\mathrm{n}) \quad \text { (eq. box } 37)
$$

Now each $[\mathrm{Q}]^{\mathrm{n}}$ matrix is multiplied only once with a single factor for each value of $n$, which is a huge performance gain compared to multiplying each $[Q]^{m}$ matrix ( $\mathrm{M}-1$ ) times.

### 4.8. PROBABILITY MODELS

### 4.8.1. INTRODUCTION

The probability models are responsible for calculating the $W$ and $P$ matrices (see previous sections) containing the relative weight fractions and probability parameters respectively. The probability parameters are derived using Markovian statistics. The rank of the matrices depends on the number of components $G$ in the mixed-layer and the Reichweite R.

The Reichweite or Reach is an important concept. The value for $R$ denotes what number of previous components (in a stack of components) still influence the probability determining the type of the following component. With other words, for:

| $R=0 ;$ | the type of the next component does not depend <br> on the previous components, |
| :--- | :--- |
| $R=1 ;$ | the type of the next component depends on the <br> type of the previous component, |
| $R=2 ;$ | the type of the next component depends on the <br> types of the previous two components, |
| etc. |  |

There are a number of general relations between the weight fractions $W$ and probabilities $P$ detailed below. They are valid regardless of the value of $R$ or $G$. These are detailed below. For a more in-depth explanation we refer to Drits \& Tchoubar (1990). For stacks composed of $G$ types of layers, we can write:

```
    \(\mathrm{W}_{\mathrm{i}}=\mathrm{N}_{\mathrm{i}} / \mathrm{N}_{\text {max }} \quad\) where \(i \quad \in\{1,2, \ldots, G\}\)
    \(\mathrm{W}_{\mathrm{ij}}=\mathrm{N}_{\mathrm{ij}} /\left(\mathrm{N}_{\text {max }}-1\right) \quad\) where \(i, j \in\{1,2, \ldots, G\}\)
\(\mathrm{W}_{\mathrm{ijk}}=\mathrm{N}_{\mathrm{ijk}} /\left(\mathrm{N}_{\max }-2\right) \quad\) where \(i, j, k \in\{1,2, \ldots, G\}\)
        !
    etc.
    with:
\(W_{i j}=W_{i} \cdot P_{i j} \quad W_{i j k}=W_{i j} \cdot P_{i j k} \quad \cdots\)
\(\sum_{\mathrm{i}}^{\mathrm{G}} \quad \mathrm{W}_{\mathrm{i}}=1 \quad \sum_{\mathrm{i}}^{\mathrm{G}} \sum_{\mathrm{j}}^{\mathrm{G}} \quad \mathrm{W}_{\mathrm{ij}}=1 \quad \ldots\)
\(\sum_{j}^{G} \quad P_{i j}=1 \quad \sum_{k}^{G} \quad P_{i j k}=1 \quad \ldots\)
```

(eq. box 38)
(eq. box 39)

In the following sections a description is made how to setup the matrices used in the calculations for different combinations of $R$ and G. An important step in this process is the selection of independent parameters. A modeller is free to choose these, however for PyXRD it was chosen to make the definition of the independent parameters as much as possible identical to those used in the Sybilla ${ }^{\circledR}$ model created by Chevron ETC, to facilitate (future) exchange of models and comparison of results.

## W AND P MATRIX LAYOUTS

The general expressions for the $W$ and $P$ matrix for different combinations of $R$ and $G$ can be generalized. To illustrate this, the matrices for an R0 or R1 model and for an R2 with G components model are shown below.

The expressions for the W and P matrix for R0 and R1 models are:

$$
\mathrm{W}=\left[\begin{array}{cccc}
\mathrm{W}_{1} & 0 & \ldots & 0 \\
0 & \mathrm{~W}_{2} & \ldots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \ldots & \mathrm{~W}_{\mathrm{G}} \\
\mathrm{P}_{11} & \mathrm{P}_{12} & \ldots & \mathrm{P}_{1 \mathrm{G}} \\
\mathrm{P} & {\left[\begin{array}{cccc}
\mathrm{P}_{21} & \mathrm{P}_{22} & \ldots & \mathrm{P}_{2 \mathrm{G}} \\
\vdots & \vdots & & \vdots
\end{array}\right]} \\
\mathrm{P}_{\mathrm{G} 1} & \mathrm{P}_{\mathrm{G} 2} & \ldots & \mathrm{P}_{\mathrm{GG}}
\end{array}\right.
$$

(eq. box 40)
(eq. box 41)

Observe that these matrices are of size GxG.

For an R2 model, the basic layout is preserved, however each of the elements in the W and P matrices (e.g. W1 or P11) are replaced by submatrices of size GxG:

(eq. box 42)

This increases the size of the complete $W$ or $P$ matrix to $G^{2} x G^{2}$.
In general, for a model with a Reichweite $R$ and $G$ components, the final $W$ and $P$ matrix will have a size of GRxGR. They can be created using the general layout of equations 42 and by replacing the elements recursively G-1 times by sub-matrices of the following generalised form:

(eq. box 43)

The "..." indices are to be replaced with the indices of the parameters the sub-matrix is replacing in the parent matrix. E.g. when replacing the initial Wi elements for an R3 model, the "..." index would be replaced with the value of the " $i$ " index of the replaced Wi parameter. The result will be a matrix containing Wij parameters. Since we are creating a matrix for an R3 model, there need to be in total 2 rounds of replacements. This means we need to replace every Wij parameter with another sub-matrix in which the "..." index is this time replaced with the value ij index values of the replaced Wij parameter. We have then made G-1 recursive replacements and the matrix will have a size of G3xG3 and contain parameters of the form Wijk.

## PARAMETER AND MATRIX INDEXATION

Simple relationships can be derived to obtain the matrix column and row indexes from the parameter indexes and vice-versa.

W parameter indexes to column and row indexes:
$\mathrm{x}=\mathrm{y}=\sum_{\mathrm{i}=1}^{\mathrm{Z}} \mathrm{z}_{\mathrm{i}} \cdot \mathrm{G}^{\mathrm{R} /-\mathrm{i}}$

> (eq. box 44)
in which:
$x$ the W matrix column index
$y \quad$ the $W$ matrix row index
Z the number of indexes in the $W$ parameter (e.g. 2 for $W 11$ )
zi the value of the i-th $W$ parameter index (e.g. z1 = 2 for W 21 )
G the number of components
$R^{\prime} \quad R$, but with a lower limit of 1 , as in: $R^{\prime}:((R>1) \rightarrow R) \wedge((R \leqslant$ 1) $\rightarrow$ 1)

The opposite relation for $W$ parameters is:
$\mathrm{z}_{\mathrm{i}}=\left(\left\lfloor\frac{\mathrm{x}-1}{\mathrm{G}^{\mathrm{R}-\mathrm{i}}}\right\rfloor \operatorname{modG}\right)+1$
in which:
$z_{i} \quad$ the value of the $i$-th $W$ parameter index (e.g. $z_{1}=2$ for $W_{21}$ )
G the number of components
$R^{\prime} \quad R$, but with a lower limit of 1 , as in: $R^{\prime}:((R>1) \rightarrow R) \wedge((R \leqslant$ 1) $\rightarrow$ 1)
$x$ the $W$ matrix column index (can be replaced with the row index since $\quad x=y$ )
$P$ parameter indexes to column and row indexes:

$$
\begin{aligned}
& \mathrm{x}=\sum_{\mathrm{i}=1}^{\mathrm{Z}-1} \mathrm{z}_{\mathrm{i}} \cdot \mathrm{G}^{\mathrm{R} /-\mathrm{i}} \\
& \mathrm{y}=\sum_{\mathrm{i}=2}^{\mathrm{Z}} \mathrm{z}_{\mathrm{i}} \cdot \mathrm{G}^{\mathrm{R} /-\mathrm{i}}
\end{aligned}
$$

in which:
$Z \quad$ the number of indexes in the $P$ parameter (e.g. 3 for $P_{123}$ )
zi the value of the i-th W parameter index (e.g. $z_{1}=3$ for $\mathrm{P}_{321}$ )
G the number of components
$R^{\prime} \quad R$, but with a lower limit of 1 , as in: $R^{\prime}:((R>1) \rightarrow R) \wedge((R \leqslant$ 1) $\rightarrow$ 1)
$x \quad$ the $P$ matrix column index
y the P matrix row index
The opposite relation for $P$ parameters is:
for $i \in\{1,2, \ldots, G\}$
$\mathrm{z}_{\mathrm{i}}=\left(\left\lfloor\frac{\mathrm{x}-1}{\mathrm{G}^{\mathrm{R}-\mathrm{i}}}\right\rfloor \bmod \mathrm{G}\right)+1$
for $i=G:$
(eq. box 47)
$\mathrm{z}_{\mathrm{i}}=\left(\left\lfloor\frac{\mathrm{y}-1}{\mathrm{G}^{\mathrm{R}-\mathrm{i}}}\right\rfloor \operatorname{modG}\right)+1$
in which:
$z_{i} \quad$ the value of the $i$-th $W$ parameter index (e.g. $z_{1}=2$ for $W_{21}$ )
G the number of components
$R^{\prime} \quad R$, but with a lower limit of 1 , as in: $R^{\prime}:((R>1) \rightarrow R) \wedge((R \leqslant$ 1) $\rightarrow$ 1)
$x$ the $W$ matrix column index (can be replaced with the row index since $\quad x=y$ )

### 4.8.2. RO MODELS - RANDOM INTERLAYERING

In this model the chance of finding any type of layer after another type of layer equals the relative weight of that layer in the whole stack. This type of disorder is actually a specific type of R1 ordering where for a stack containing G different types of layers we can write:
$\mathrm{P}_{\mathrm{ga}}=\mathrm{W}_{\mathrm{a}}$ and $\mathrm{W}_{\mathrm{ga}}=\mathrm{W}_{\mathrm{g}} * \mathrm{P}_{\mathrm{ga}}=\mathrm{W}_{\mathrm{g}} * \mathrm{~W}_{\mathrm{a}}$
$\mathrm{P}_{\mathrm{gb}}=\mathrm{W}_{\mathrm{b}}$ and $\mathrm{W}_{\mathrm{gb}}=\mathrm{W}_{\mathrm{g}} * \mathrm{P}_{\mathrm{gb}}=\mathrm{W}_{\mathrm{g}} * \mathrm{~W}_{\mathrm{b}}$
$\mathrm{P}_{\mathrm{gc}}=\mathrm{W}_{\mathrm{c}} a n d \mathrm{~W}_{\mathrm{gb}}=\mathrm{W}_{\mathrm{g}} * \mathrm{P}_{\mathrm{gc}}=\mathrm{W}_{\mathrm{g}} * \mathrm{~W}_{\mathrm{c}}$
(eq. box 48)
$\mathrm{P}_{g G}=\mathrm{W}_{\mathrm{G}}$ and $\mathrm{W}_{g G}=\mathrm{W}_{\mathrm{g}} * \mathrm{P}_{g G}=\mathrm{W}_{\mathrm{g}} * \mathrm{~W}_{\mathrm{G}}$ withg $\in\{1,2, \ldots, \mathrm{G}\}$
In addition to the above relations, the sum of all the relative weights should equal one (see equation box 39):
$\sum_{i=1}^{G} W_{i}=1$
Therefore, since we have $G$ weight fraction parameters and we have G+1 relations, we only need to choose G-1 independent parameters to be able to calculate all weight fractions and related probabilities. These G-1 parameters are chosen as such so that they can all be described by the following weight fraction definition:
$\mathrm{Fw}_{\mathrm{g}}=\frac{\mathrm{W}_{\mathrm{g}}}{\sum_{\mathrm{i}=\mathrm{g}}^{\mathrm{G}} \mathrm{W}_{\mathrm{i}}}$ withg $\in\{1,2, \ldots, \mathrm{G}-1\}$ (eq. box 49)

Using the above definition we can derive that:
$\mathrm{W}_{\mathrm{g}}=\mathrm{Fw}_{\mathrm{g}} * \sum_{\mathrm{i}=\mathrm{g}}^{\mathrm{G}} \quad \mathrm{W}_{\mathrm{i}}$ for every $g \in\{1,2, \ldots, G\}$ (eq. box 50)
and using equation 39 , we can also derive that:

$$
\begin{equation*}
\sum_{\mathrm{i}=1}^{\mathrm{G}} \quad \mathrm{~W}_{\mathrm{i}}=\sum_{\mathrm{i}=1}^{\mathrm{g}-1} \quad \mathrm{~W}_{\mathrm{i}}+\sum_{\mathrm{i}=\mathrm{g}}^{\mathrm{G}} \quad \mathrm{~W}_{\mathrm{i}} \tag{eq.box51}
\end{equation*}
$$

$\sum_{\mathrm{i}=\mathrm{g}}^{\mathrm{G}} \quad \mathrm{W}_{\mathrm{i}}=1-\sum_{\mathrm{i}=1}^{\mathrm{g}-1} \quad \mathrm{~W}_{\mathrm{i}}$ for every $g \in\{1,2, \ldots, \mathrm{G}\}$
If we are considering the first ratio $\mathrm{Fw}_{1}$, then in equation $50 \mathrm{~g}=1$ and, using equation 39 , can be written as:

$$
\begin{gather*}
\mathrm{W}_{1}=\mathrm{Fw}_{1} \cdot \sum_{\mathrm{i}=1}^{\mathrm{G}} \mathrm{~W}_{\mathrm{i}} \\
\mathrm{~W}_{1}=\mathrm{Fw}_{1} \tag{eq.box52}
\end{gather*}
$$

Or, with other words, the first fraction equals the weight fraction for the first component. Knowing this, the other weight fractions can be derived in sequence by combining the relations in boxes 50 and 51. E.g. for $g=2$ we can write:
$\mathrm{W}_{2}=\mathrm{Fw}_{2} \cdot \sum_{\mathrm{i}=2}^{\mathrm{G}} \quad \mathrm{W}_{\mathrm{i}}$
(eq. box 53)
and since:
$\sum_{\mathrm{i}=2}^{\mathrm{G}} \quad \mathrm{W}_{\mathrm{i}}=1-\sum_{\mathrm{i}=1}^{1} \quad \mathrm{~W}_{\mathrm{i}}=1-\mathrm{W}_{1}$
(eq. box 54)
the first expression becomes:
$\mathrm{W}_{2}=\mathrm{Fw}_{2} \cdot\left(1-\mathrm{W}_{1}\right)$
(eq. box 55)
As can be derived from the above equations, these RO expression can be extended for any number of components. In fact, the implementation in PyXRD comprises a generalised probability model that can handle any number of layers. In practice however, there is little need for a 100 component mixed layer model, so the upper limit has been set to 6 different components (for now).
4.8.3. R1 MODELS

PyXRD has R1 models available for mixed-layers with up to 4 different components.

## TWO-COMPONENT R1 MODEL

For two-component ( $\mathrm{G}=2$ ) R1 models, the independent parameters are $\mathrm{W}_{1}$ and $\mathrm{P}_{11}\left(\mathrm{ifW}_{1} \leqslant 0.5\right)$ or $\mathrm{P}_{22}\left(\mathrm{ifW} W_{1}>0.5\right)$. The other parameters in this model can then be calculated using these two parameters:
$\mathrm{W}_{2}=1-\mathrm{W}_{1}$
$i f W_{0} \leqslant 0.5$ :
$P_{12}=1-P_{11}$
$\mathrm{P}_{21}=\mathrm{W}_{1} \cdot \frac{\mathrm{P}_{12}}{\mathrm{~W}_{2}}$
$P_{22}=1-P_{21}$
(eq. box 56)
if $\mathrm{W}_{0}>0.5$ :
$P_{21}=1-P_{22}$
$\mathrm{P}_{12}=\mathrm{W}_{2} \cdot \frac{\mathrm{P}_{21}}{\mathrm{~W}_{1}}$
$\mathrm{P}_{11}=1-\mathrm{P}_{12}$

## THREE-COMPONENT R1 MODEL

For three-component ( $\mathrm{G}=3$ ) R1 models, the first two independent parameters are identical to the two-component model: $\mathrm{W}_{1}$ and either $\mathrm{P}_{11}\left(\mathrm{ifW}_{1} \leqslant 0.5\right)$ or $\mathrm{P}_{\mathrm{xx}}\left(\mathrm{ifW} \mathrm{F}_{1}>0.5\right)$, the latter is defined as:
$\mathrm{P}_{\mathrm{xx}}=\frac{\mathrm{W}_{22}+\mathrm{W}_{23}+\mathrm{W}_{32}+\mathrm{W}_{33}}{\mathrm{~W}_{2}+\mathrm{W}_{3}}$
(eq. box 57)
The other four parameters are chosen to be the following fractions:

$$
\begin{gather*}
\mathrm{FW}_{1}=\frac{\mathrm{w}_{2}}{\mathrm{~W}_{3}+\mathrm{W}_{2}} \\
\mathrm{Fw}_{2}=\frac{\mathrm{w}_{22}+\mathrm{W}_{23}}{\mathrm{w}_{22}+\mathrm{W}_{23}+\mathrm{W}_{32}+\mathrm{w}_{33}}  \tag{eq.box58}\\
\mathrm{FW}_{3}=\frac{\mathrm{W}_{22}}{\mathrm{~W}_{22}+\mathrm{W}_{23}} \\
\mathrm{FW}_{4}=\frac{\mathrm{W}_{23}}{\mathrm{~W}_{32}+\mathrm{W}_{33}}
\end{gather*}
$$

The primary weight fractions $W_{2}$ and $W_{3}$ can be calculated as follows:
$\mathrm{W}_{2}=\left(1-\mathrm{W}_{1}\right) \cdot \mathrm{FW}_{1}$
$\mathrm{W}_{3}=1-\mathrm{W}_{1}-\mathrm{W}_{2}$
(eq. box 59)
If $W_{1} \leqslant 0.5$ :
Since:
$\mathrm{W}_{1}=\mathrm{W}_{11}+\mathrm{W}_{21}+\mathrm{W}_{31} \Rightarrow \mathrm{P}_{11}=\frac{\mathrm{W}_{1}-\mathrm{W}_{21}-\mathrm{W}_{31}}{\mathrm{~W}_{1}}$
$\mathrm{W}_{2}=\mathrm{W}_{12}+\mathrm{W}_{22}+\mathrm{W}_{32} \Rightarrow \mathrm{P}_{12}=\frac{\mathrm{W}_{2}-\mathrm{W}_{22}-\mathrm{W}_{32}}{\mathrm{~W}_{1}}$
$\mathrm{W}_{3}=\mathrm{W}_{13}+\mathrm{W}_{23}+\mathrm{W}_{33} \Rightarrow \mathrm{P}_{13}=\frac{\mathrm{W}_{3}-\mathrm{W}_{23}-\mathrm{W}_{33}}{\mathrm{~W}_{1}}$
We can write:
$\left(\mathrm{P}_{12}+\mathrm{P}_{13}\right) \cdot \mathrm{W}_{1}=\mathrm{W}_{2}+\mathrm{W}_{3}-\left(\mathrm{W}_{22}+\mathrm{W}_{23}+\mathrm{W}_{32}+\mathrm{W}_{33}\right)=\mathrm{W}_{2}+\mathrm{W}_{3}-\mathrm{W}_{\mathrm{xx}}$ $\mathrm{W}_{\mathrm{xx}}=\mathrm{W}_{2}+\mathrm{W}_{3}-\mathrm{W}_{1} \cdot\left(\mathrm{P}_{12}+\mathrm{P}_{13}\right)$

Since $\mathrm{P}_{11}+\mathrm{P}_{12}+\mathrm{P}_{13}=1$ we can change this to:

$$
\mathrm{W}_{\mathrm{xx}}=\mathrm{W}_{2}+\mathrm{W}_{3}-\mathrm{W}_{1} \cdot\left(1-\mathrm{P}_{11}\right)
$$

(eq. box 60)
If $W_{1}>0.5$ :
$\mathrm{W}_{\mathrm{xx}}=\left(1.0-\mathrm{W}_{1}\right) \cdot \mathrm{P}_{\mathrm{xx}}$
(eq. box 61)
From that point on the calculation is fairly straightforward:

$$
\begin{align*}
& \mathrm{W}_{22}=\mathrm{W}_{\mathrm{xx}} \cdot \mathrm{Fw}_{2} \cdot \mathrm{FW}_{3} \\
& \mathrm{~W}_{23}=\mathrm{W}_{\mathrm{xx}} \cdot \mathrm{Fw}_{2} \cdot\left(1-\mathrm{Fw}_{3}\right) \\
& \mathrm{P}_{22}=\frac{\mathrm{W}_{22}}{\mathrm{~W}_{2}} i f \mathrm{~W}_{2}>0 \mathrm{else} 0 \\
& P_{21}=1-P_{22}-P_{23} \\
& \mathrm{~W}_{32}=\mathrm{W}_{\mathrm{xx}} \cdot\left(1-\mathrm{Fw}_{2}\right) \cdot \mathrm{Fw}_{4} \\
& \mathrm{~W}_{33}=\mathrm{W}_{\mathrm{xx}} \cdot\left(1-\mathrm{Fw}_{2}\right) \cdot\left(1-\mathrm{FW}_{4}\right) \\
& \mathrm{P}_{32}=\frac{\mathrm{W}_{32}}{\mathrm{~W}_{3}} i f \mathrm{~W}_{3}>0 e l s e 0  \tag{eq.box62}\\
& \mathrm{P}_{33}=\frac{\mathrm{W}_{33}}{\mathrm{~W}_{3}} \mathrm{if} \mathrm{~W}_{3}>0 \mathrm{else} 0 \\
& P_{31}=1-P_{33}-P_{31} \\
& \mathrm{P}_{12}=\frac{\mathrm{W}_{2}-\mathrm{W}_{22}-\mathrm{W}_{32}}{\mathrm{~W}_{1}} \text { if } \mathrm{W}_{1}>0 \mathrm{else} 0 \\
& \mathrm{P}_{13}=\frac{\mathrm{W}_{3}-\mathrm{W}_{23}-\mathrm{W}_{33}}{\mathrm{~W}_{1}} \text { ifW } \mathrm{W}_{1}>0 \mathrm{else} 0 \\
& \mathrm{P}_{11}=1-\mathrm{P}_{12}-\mathrm{P}_{13} i f \mathrm{~W}_{1}>0.5 \text { else }_{11} \text { is given } \\
& \text { At this point we know all probability parameters } \mathrm{P}_{\mathrm{ij}} \text {. Together with the } \\
& \text { primary weight fractions } W_{1}, W_{2} \text { and } W_{3} \text {, it possible to calculate any } \\
& \text { unknown } \mathrm{W}_{\mathrm{ij}} \text { using the equations from box } 39 .
\end{align*}
$$

## FOUR-COMPONENT R1 MODEL

As with previous R1 models, the first two independent parameters are $\mathrm{W}_{1}$ and either $\mathrm{P}_{11}\left(\mathrm{ifW} W_{1} \leqslant 0.5\right)$ or $\mathrm{P}_{22}\left(\right.$ ifW $\left.\mathrm{i}_{1}>0.5\right)$. The other 10 parameters are chosen to be the following fractions:

$$
\begin{array}{cc}
\mathrm{FW}_{1}=\frac{\mathrm{W}_{2}}{\mathrm{~W}_{2}+\mathrm{W}_{3}+\mathrm{W}_{4}} & \mathrm{FW}_{2}=\frac{\mathrm{W}_{3}}{\mathrm{~W}_{3}+\mathrm{W}_{4}} \\
\mathrm{FW}_{3}=\frac{\mathrm{W}_{22}+\mathrm{W}_{23}+\mathrm{W}_{24}}{\sum_{\mathrm{i}=2}^{4} \sum_{\mathrm{j}=2}^{4} \quad \mathrm{~W}_{\mathrm{ij}}} & \mathrm{FW}_{4}=\frac{\mathrm{W}_{32}+\mathrm{W}_{33}+\mathrm{W}_{34}}{\sum_{\mathrm{i}=3}^{4} \sum_{\mathrm{j}=2}^{4} \quad \mathrm{~W}_{\mathrm{ij}}} \\
\mathrm{FW}_{22}=\frac{\mathrm{W}_{22}}{\mathrm{~W}_{22}+\mathrm{W}_{23}+\mathrm{W}_{24}} & \mathrm{FW}_{23}=\frac{\mathrm{W}_{23}}{\mathrm{~W}_{23}+\mathrm{W}_{24}} \\
\mathrm{FW}_{32}=\frac{\mathrm{W}_{32}}{\mathrm{~W}_{32}+\mathrm{W}_{33}+\mathrm{W}_{34}} & \mathrm{FW}_{33}=\frac{\mathrm{W}_{33}}{\mathrm{~W}_{33}+\mathrm{W}_{34}}  \tag{eq.box63}\\
\mathrm{FW}_{42}=\frac{\mathrm{W}_{42}}{\mathrm{~W}_{42}+\mathrm{W}_{43}+\mathrm{W}_{44}} & \mathrm{FW}_{43}=\frac{\mathrm{W}_{43}}{\mathrm{~W}_{43}+\mathrm{W}_{44}}
\end{array}
$$

(eq. box 63)

Again, the primary weight fractions can be easily calculated from these fractions:

$$
\begin{gathered}
\mathrm{W}_{2}=\left(1-\mathrm{W}_{1}\right) \cdot \mathrm{FW}_{1} \\
\mathrm{~W}_{3}=\left(1-\mathrm{W}_{1}-\mathrm{W}_{2}\right) \cdot \mathrm{FW}_{2} \\
\mathrm{~W}_{4}=1-\mathrm{W}_{1}-\mathrm{W}_{2}-\mathrm{W}_{3}
\end{gathered}
$$

(eq. box 64)

Then, if $W_{1} \leq 0.5$, we can calculate $W_{x x}$ using the following formula, derived in the same way as for the 3 component R1 model:
$\mathrm{W}_{\mathrm{xx}}=\mathrm{W}_{1} \cdot\left(\mathrm{P}_{11}-1\right)+\mathrm{W}_{2}+\mathrm{W}_{3}+\mathrm{W}_{4}$
(eq. box 65)
If $\mathrm{W} 1>0.5, \mathrm{Wxx}$ is calculated as:
$\mathrm{W}_{\mathrm{xx}}=\mathrm{P}_{\mathrm{xx}} \cdot\left(\mathrm{W}_{2}+\mathrm{W}_{3}+\mathrm{W}_{4}\right)$
(eq. box 66)
From that point on the calculation is again fairly straightforward, first we calculate a number of partial sums:

$$
\begin{gather*}
\mathrm{W}_{2 \mathrm{x}}=\mathrm{W}_{22}+\mathrm{W}_{23}+\mathrm{W}_{24}=\mathrm{W}_{\mathrm{xx}} \cdot \mathrm{FW}_{3} \\
\mathrm{~W}_{\mathrm{yx}}=\mathrm{W}_{32}+\mathrm{W}_{33}+\mathrm{W}_{34}+\mathrm{W}_{42}+\mathrm{W}_{43}+\mathrm{W}_{44}=\left(\mathrm{W}_{\mathrm{xx}}-\mathrm{W}_{2 \mathrm{x}}\right) \\
\mathrm{W}_{3 \mathrm{x}}=\mathrm{W}_{32}+\mathrm{W}_{33}+\mathrm{W}_{34}=\mathrm{W}_{\mathrm{yx}} \cdot \mathrm{FW}_{4}  \tag{eq.box67}\\
\mathrm{~W}_{4 \mathrm{x}}=\mathrm{W}_{42}+\mathrm{W}_{43}+\mathrm{W}_{44}=\mathrm{W}_{\mathrm{yx}}-\mathrm{W}_{3 \mathrm{x}}
\end{gather*}
$$

Then we can calculate some of the weight fractions and all of the probabilities as follows:

$$
\begin{align*}
& \mathrm{W}_{22}=\mathrm{Fw}_{22} \cdot \mathrm{~W}_{2 \mathrm{x}} \\
& \mathrm{~W}_{23}=\mathrm{Fw}_{23} \cdot\left(\mathrm{~W}_{2 \mathrm{x}}-\mathrm{W}_{22}\right) \\
& \mathrm{W}_{24}=\mathrm{W}_{2 \mathrm{x}}-\mathrm{W}_{22}-\mathrm{W}_{23} \\
& \mathrm{~W}_{32}=\mathrm{Fw}_{32} \cdot \mathrm{~W}_{3 \mathrm{x}} \\
& \mathrm{~W}_{33}=\mathrm{Fw}_{33} \cdot\left(\mathrm{~W}_{3 \mathrm{x}}-\mathrm{W}_{32}\right)  \tag{eq.box68}\\
& \mathrm{W}_{34}=\mathrm{W}_{3 \mathrm{x}}-\mathrm{W}_{32}-\mathrm{W}_{33} \\
& \mathrm{~W}_{42}=\mathrm{Fw}_{42} \cdot \mathrm{~W}_{4 \mathrm{x}} \\
& \mathrm{~W}_{43}=\mathrm{Fw}_{43} \cdot\left(\mathrm{~W}_{4 \mathrm{x}}-\mathrm{W}_{42}\right) \\
& \mathrm{W}_{44}=\mathrm{W}_{4 \mathrm{x}}-\mathrm{W}_{42}-\mathrm{W}_{43} \\
& \mathrm{P}_{23}=\mathrm{W}_{23} / \mathrm{W}_{2} \quad \text { or if } \mathrm{W}_{2}=0: \mathrm{P}_{23}=0 \\
& \mathrm{P}_{24}=\mathrm{W}_{24} / \mathrm{W}_{2} \quad \text { or if } \mathrm{W}_{2}=0: \mathrm{P}_{24}=0 \\
& P_{21}=1-P_{22}-P_{23}-P_{24} \\
& \mathrm{P}_{32}=\mathrm{W}_{32} / \mathrm{W}_{3} \quad \text { or if } \mathrm{W}_{3}=0: \mathrm{P}_{32}=0 \\
& \mathrm{P}_{33}=\mathrm{W}_{33} / \mathrm{W}_{3} \quad \text { or if } \mathrm{W}_{3}=0: \mathrm{P}_{33}=0 \\
& \mathrm{P}_{34}=\mathrm{W}_{34} / \mathrm{W}_{3} \quad \text { or if } \mathrm{W}_{3}=0: \mathrm{P}_{34}=0 \\
& P_{31}=1-P_{32}-P_{33}-P_{34} \\
& \mathrm{P}_{42}=\frac{\mathrm{W}_{42}}{\mathrm{~W}_{4}} \quad \text { or if } \mathrm{W}_{4}=0: \mathrm{P}_{42}=0 \\
& \mathrm{P}_{43}=\frac{\mathrm{W}_{43}}{\mathrm{~W}_{4}} \quad \text { or if } \mathrm{W}_{4}=0: \mathrm{P}_{43}=0 \\
& \mathrm{P}_{44}=\frac{\mathrm{W}_{44}}{\mathrm{~W}_{4}} \quad \text { or if } \mathrm{W}_{4}=0: \mathrm{P}_{44}=0 \\
& P_{41}=1-P_{42}-P_{43}-P_{44} \\
& \mathrm{P}_{12}=\frac{\mathrm{W}_{2}-\mathrm{W}_{22}-\mathrm{W}_{32}-\mathrm{W}_{42}}{\mathrm{~W}_{1}} \quad \text { or if } \mathrm{W}_{1}=0: \mathrm{P}_{12}=0 \\
& \mathrm{P}_{13}=\frac{\mathrm{W}_{3}-\mathrm{W}_{23}-\mathrm{W}_{33}-\mathrm{W}_{43}}{\mathrm{~W}_{1}} \quad \text { or if } \mathrm{W}_{1}=0: \mathrm{P}_{13}=0 \\
& \mathrm{P}_{14}=\frac{\mathrm{W}_{4}-\mathrm{W}_{24}-\mathrm{W}_{34}-\mathrm{W}_{44}}{\mathrm{~W}_{1}} \quad \text { or if } \mathrm{W}_{1}=0: \mathrm{P}_{14}=0 \\
& P_{11}=1-P_{12}-P_{13}-P_{14} \quad \text { ifW } 1>0.5 \text { else }_{11} \text { isgiven }
\end{align*}
$$

(eq. box 69)

At this point we know all probability parameters $\mathrm{P}_{\mathrm{ij}}$. Together with the primary weight fractions $W_{1}, W_{2}, W_{3}$ and $W_{4}$, it possible to calculate any unknown $\mathrm{W}_{\mathrm{ij}}$ using the equations from box 39 .

### 4.8.4. R2 MODELS

PyXRD has R2 models available for models with up to 3 different components.

## TWO-COMPONENT R2 MODEL

This is one of the few exceptions where the choice of independent parameters differs from Sybilla. The reason is that Sybilla implements a restricted version, not allowing for the full range of possibilities. PyXRD does not have these constraints. The result is that PyXRD requires two more parameters (4 in tolal) compared with Sybilla.

As with previous models, the first independent parameter is $\mathrm{W}_{1}$ and either $\mathrm{P}_{112}\left(\mathrm{ifW}_{1} \leqslant 2 / 3\right)$ or $\mathrm{P}_{211}\left(\mathrm{ifW}_{1}>2 / 3\right), \mathrm{P}_{21}$ and either $\mathrm{P}_{122}$ (ifW ${ }_{1} \leqslant$ 0.5 ) or $\mathrm{P}_{211}\left(\mathrm{ifW}_{1}>0.5\right)$.

The calculation proceeds as follows:

$$
\begin{aligned}
& \text { IfW } W_{1} \leqslant 2 / 3: \quad \text { IfW } W_{1} \leqslant 0.5: \\
& \mathrm{P}_{211}=\mathrm{P}_{112} \cdot \frac{\mathrm{~W}_{11}}{\mathrm{~W}_{21}} \mathrm{P}_{221}=\mathrm{P}_{211} \cdot \frac{\mathrm{~W}_{12}}{\mathrm{~W}_{22}} \\
& \text { else: else: } \\
& \mathrm{P}_{112}=\mathrm{P}_{211} \cdot \frac{\mathrm{~W}_{21}}{\mathrm{~W}_{11}} \mathrm{P}_{122}=\mathrm{P}_{221} \cdot \frac{\mathrm{~W}_{22}}{\mathrm{~W}_{12}} \quad \text { (eq. box 70) } \\
& \mathrm{P}_{212}=1-\mathrm{P}_{211} \mathrm{P}_{121}=1-\mathrm{P}_{122} \\
& \mathrm{P}_{111}=1-\mathrm{P}_{112} \mathrm{P}_{222}=1-\mathrm{P}_{221} \\
& \mathrm{~W}_{2}=1-\mathrm{W}_{1} \\
& \mathrm{P}_{22}=1-\mathrm{P}_{21} \\
& \\
& \mathrm{~W}_{21}=\mathrm{W}_{2} \cdot \mathrm{P}_{21} \\
& \mathrm{~W}_{22}=\mathrm{W}_{2} \cdot \mathrm{P}_{22} \\
& \mathrm{~W}_{12}=\mathrm{W}_{21} \\
& \mathrm{~W}_{11}=\mathrm{W}_{1}-\mathrm{W}_{21}
\end{aligned}
$$

## THREE-COMPONENT R2 MODEL

The three-component R2 model is restricted in the sense that the weight fraction of the first component must be equal to or larger then $50 \%$ and no 2 nd or 3 d type component can follow or precede another 2nd or 3d type component. This restriction results into the following relations:

$$
\begin{gathered}
\mathrm{P}_{22}=\mathrm{P}_{23}=0 \Rightarrow \mathrm{P}_{21}=1 \\
\mathrm{P}_{32}=\mathrm{P}_{33}=0 \Rightarrow \mathrm{P}_{31}=1 \\
\\
\mathrm{P}_{222}=\mathrm{P}_{223}=0 \Rightarrow \mathrm{P}_{221}=1 \\
\mathrm{P}_{232}=\mathrm{P}_{233}=0 \Rightarrow \mathrm{P}_{231}=1 \\
\mathrm{P}_{322}=\mathrm{P}_{323}=0 \Rightarrow \mathrm{P}_{321}=1 \\
\mathrm{P}_{332}=\mathrm{P}_{333}=0 \Rightarrow \mathrm{P}_{331}=1 \\
\\
\mathrm{~W}_{21}=\mathrm{W}_{12}=\mathrm{W}_{2} \\
\mathrm{~W}_{31}=\mathrm{W}_{13}=\mathrm{W}_{3} \\
\mathrm{~W}_{11}=\mathrm{W}_{1}
\end{gathered}
$$

Because of these restrictions, the number of independent variables is reduced to only 6 . They are chosen to be $\mathrm{W}_{1}$, either $\mathrm{P}_{111}$ (if0.5 $\leqslant \mathrm{W}_{1} \leqslant$ $2 / 3$ ) or $\mathrm{P}_{212}$ (if $2 / 3 \leqslant \mathrm{~W}_{1} \leqslant 1$ ), and the following four fractions:

$$
\begin{gathered}
\mathrm{FW}_{1}=\frac{\mathrm{W}_{1}}{\mathrm{~W}_{1}+\mathrm{W}_{2}} \\
\mathrm{Fw}_{2}=\frac{\mathrm{W}_{212}+\mathrm{W}_{213}}{\mathrm{~W}_{212}+\mathrm{W}_{213}+\mathrm{W}_{312}+\mathrm{W}_{313}} \\
\mathrm{FW}_{3}=\frac{\mathrm{W}_{212}}{\mathrm{~W}_{212}+\mathrm{W}_{213}} \\
\mathrm{FW}_{4}=\frac{\mathrm{W}_{312}}{\mathrm{~W}_{312}+\mathrm{W}_{313}}
\end{gathered}
$$

(eq. box 72)

The calculation of the other parameters proceeds as follows:

$$
\begin{gathered}
\mathrm{W}_{2}=\mathrm{FW}_{1} \cdot\left(1-\mathrm{W}_{1}\right) \\
\mathrm{W}_{3}=1-\mathrm{W}_{1}-\mathrm{W}_{2} \\
\mathrm{P}_{212}=\frac{\mathrm{Fw}_{2} \cdot \mathrm{Fw}_{1}}{\mathrm{~W}_{1}} \cdot\left[\mathrm{~W}_{11} \cdot\left(\mathrm{P}_{111}-1\right)+2\right] \quad \text { if0.5 } \leqslant \mathrm{W}_{1} \leqslant 2 / 3 \\
\mathrm{P}_{213}=\mathrm{P}_{212} \cdot\left(\frac{1}{\mathrm{FW}_{3}}-1\right) \quad \text { or ifFw }{ }_{3}=0 \Rightarrow \mathrm{P}_{213}=1 \\
\mathrm{~W}_{212}=\mathrm{P}_{212} \cdot \mathrm{~W}_{21}=\mathrm{P}_{212} \cdot \mathrm{~W}_{2} \\
\mathrm{~W}_{213}=\mathrm{P}_{213} \cdot \mathrm{~W}_{2} \\
\mathrm{~W}_{211}=1-\mathrm{W}_{212}-\mathrm{W}_{213}
\end{gathered}
$$

$$
\begin{gathered}
\mathrm{W}_{312}+\mathrm{W}_{313}=\frac{1-\mathrm{Fw}_{2}}{\mathrm{Fw}_{3} \cdot \mathrm{Fw}_{4}} \cdot \mathrm{~W}_{212} \text { or ifFw }{ }_{3}=0 \mathrm{orFw}_{4}=0 \Rightarrow \mathrm{~W}_{312}+\mathrm{W}_{313}=0 \\
\mathrm{~W}_{312}=\mathrm{Fw}_{4} \cdot\left(\mathrm{~W}_{312}+\mathrm{W}_{313}\right) \\
\mathrm{W}_{313}=\left(\frac{1}{\mathrm{Fw}_{4}}-1\right) \cdot \mathrm{W}_{312} \mathrm{or} \mathrm{ifFw}_{4}=0 \Rightarrow \mathrm{~W}_{313}=1 \\
\mathrm{~W}_{311}=1-\mathrm{W}_{312}-\mathrm{W}_{313} \\
\mathrm{~W}_{111}=\mathrm{W}_{11}-\mathrm{W}_{211}-\mathrm{W}_{311}
\end{gathered}
$$

The remaining unknown parameters can be derived using the general equations as in equations 38 and 39 .

### 4.8.5. R3 MODELS

PyXRD has a single (restricted) R3 probability model built-in for a 2 component mixed layer. Because of the restrictions only 2 independent variables are needed for this model; $\mathrm{W}_{1}$ and $\mathrm{P}_{1111}$ (if $2 / 3 \leqslant \mathrm{~W}_{1}<3 / 4$ ) or $\mathrm{P}_{2112}$ (if $3 / 4 \leqslant \mathrm{~W}_{1} \leqslant 1$ ).

The restrictions for this model, that:

- only mixed layers with more than 2/3 of the first layer type can be described
- no two layers of the second type occur after each other
- the probability of finding a layer of the first type in between two layers of the second type is zero

This translates into the following conditions:
$2 / 3 \leqslant W_{1} \leqslant 1$
$\mathrm{P}_{22}=\mathrm{P}_{212}=0$
$P_{21}=P_{211}=1$
The probabilities below are undefined but are set to zero or one to make the matrix valid. The actual value actually has no meaning since the weight fractions they should be multiplied with equal zero anyway (e.g. $W_{2211}=W_{22} \cdot P_{221} \cdot P_{2211}$ and $W_{22}$ is zero since $P_{22}$ is zero):
$\mathrm{P}_{1121}=\mathrm{P}_{1211}=\mathrm{P}_{2211}=\mathrm{P}_{2121}=\mathrm{P}_{2221}=\mathrm{P}_{1221}=0$
$\mathrm{P}_{1122}=\mathrm{P}_{1212}=\mathrm{P}_{2212}=\mathrm{P}_{2122}=\mathrm{P}_{2222}=\mathrm{P}_{1222}=1$
The remaining probabilities and weight fractions can be calculated as follows and using equations 38 and 39:

$$
\begin{gathered}
\mathrm{W}_{2}=1-\mathrm{W}_{1} \\
\text { ifW } \mathrm{W}_{1}<3 / 4: \\
\mathrm{P}_{1111} \text { is given } \\
\mathrm{P}_{1112}=1-\mathrm{P}_{1111} \geqslant 3 / 4: \\
\mathrm{P}_{2112} \text { is given } \\
\mathrm{P}_{2111}=\mathrm{P}_{1112} \cdot \frac{\mathrm{~W}_{1}-2 \cdot \mathrm{~W}_{2}}{\mathrm{~W}_{2}} \\
\mathrm{P}_{2111}=1-\mathrm{P}_{2112} \\
\mathrm{P}_{2112}=1-\mathrm{P}_{2111} \\
\\
\mathrm{~W}_{111}=3 \cdot \mathrm{P}_{2111} \cdot \frac{\mathrm{~W}_{2}}{\mathrm{~W}_{1}-2 \cdot \mathrm{~W}_{2}} \\
\mathrm{P}_{1112}=1-\mathrm{P}_{1111} \\
\mathrm{~W}_{212}=\mathrm{W}_{221}=\mathrm{W}_{222}=\mathrm{W}_{122}=0 \\
\mathrm{~W}_{211}=\mathrm{W}_{121}=\mathrm{W}_{112}=1-\mathrm{W}_{1}
\end{gathered}
$$

## 5. SOFTWARE LAYOUT

The general software layout of PyXRD is schematically presented in Figure 1.

The most basic layer is inside the 'calculations' module. This module contains all the basic functions and data structures to allow fast calculations of X-ray diffraction patterns of disordered lamellar structures. In effect it is an implementation of the matrix algorithm as presented in the previous chapters. However, this layer is too basic to be of immediate use to a non-technical user. A GUI has been created to allow easier manipulation of objects. This is where the mvc framework comes into play.

The mvc framework consists of three layers: a model layer containing all the 'logic' and wrapping the data structures present in the calculation layer. On top of this layer two more layers are provided: a controller and a view. The view is the visual representation of a (or part of a) model(s) while the controller provides the link between that view and the underlying model(s). The mvc pattern is a common paradigm which allows to separate so-called 'business logic' aspects from GUI aspects, making it easier to debug these separately.

In the PyXRD source tree the models, views and controllers are grouped topic-wise, meaning that all views, controllers and models for a specific part (e.g. atoms, projects, phases, ...) are grouped in a module named accordingly. Common code is provided by the mvc module. In future releases the mvc module might become a separate dependency. For now it is included with PyXRD.

The actual calculations (as presented in the previous chapters) are fully separated from the model layer into the calculations module. This makes it easier to spread the calculations over several processes, making efficient use of multi-core processors.

Aside from these layers, there are (more technical) aspects which are not covered in this manual like input/output, plotting, refinement support, etc. For details on these we refer to the source code and the documentation therein.

## Calculations

Figure 1: PyXRD's most important software layers

### 5.1. MODEL HIERARCHY

### 5.1.1. OVERVIEW

Figure 2: Overview of the model hierarchy in PyXRD
An overview of the model hierarchy can be found in Figure 2. The topmost model is the Project, which holds references to AtomTypes, Phases, Specimens and Mixtures. Each of these can have references to each other and several other objects each of which are discussed in more detail below.

### 5.1.2. ATOMTYPES AND ATOMS

The most basic building block is the AtomType. This object bundles all the physical constants (e.g. charge, atomic weight, scattering factors, ...) for a single ion (e.g. $\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \ldots$ ) or for a small enough molecule (i.e. $\mathrm{H}_{2} \mathrm{O}$ or glycol). When a new project is created a default list of these AtomTypes is loaded, using the atomic scattering factors as published in (Waasmaier and Kirfel, 1995).

Atom objects hold a reference to one of these AtomTypes and has additional information about the position of that atom in the structure (a z coordinate) and its multiplicity (as atoms are projected, we can group them together). Lists of these atom objects are used in the Component object to describe the layers and interlayers. They also support expendable interlayers in which the $z$ coordinate of the Atom is recalculated keeping the relative alignment correct.

### 5.1.3. PHASES, COMPONENTS, ATOMRELATIONS AND

## UNITCELLPROPERTIES

Phase objects contain all the information needed to calculate a onedimensional X-ray diffraction pattern for a (mixed-layer) mineral. A Phase is built out of (i) a Probability object, (ii) an object describing the coherent scattering domain size (CSDS) and (iii) one or more Component objects which describe the different types of layers in the Phase. The Probability object describes how these layers are stacked using Markovian statistics and the Reichweite concept as detailed in chapter. The CSDS object describes what type of coherent scattering domain size distribution should be used and contains the necessary parameter values (e.g. average CSDS). Currently two types are implemented: a generic log-normal distribution and a log-normal distribution in which the average values published in Drits et al. (1997) are used and the average CSDS is the only variable. Each phase also has a $\sigma^{*}$ factor which allows to correct for incomplete preferred orientation (see chapter).

Component objects describe the size, structure, composition and (variation in) basal spacing for each layer type in that phase. A Component contains two lists of Atom objects. The first list contains
atoms in the silicate lattice while the other list contains the variable interlayer ions. This way, the silicate structure can be shared between different phases (e.g. AD and EG states) while keeping the interlayer contents separate. It also allows to automatically adjust the positions of the interlayer content in function of the basal spacing, as the size of the silicate lattice can be determined and be used as a reference plane for scaling the interlayer atom positions.

Inside Components one can also define several AtomRelations: these describe relations between atoms. One such relation are AtomRatio's, for example the octahedral composition of a dioctahedral clay mineral can be expressed as the ratio of iron atoms over the sum of iron and aluminium atoms in that octahedral position. The AtomRatio object will then make sure that the sum of both Atoms multiplicity is always 4, and that their relative amounts is controlled by a certain ratio set by the user. Both the value of the sum and the ratio can be adjusted. Another example is interlayer cation contents, which are controlled by an AtomContents object.

Another type of AtomRelation are UnitCellProperties. These objects describe the $b$ and $c$ axis length of the unti cell. This object is needed, since these properties are inter-dependent (i.e. the b-length can be calculated if the c-length is known and vice-versa) and dependent on the composition (e.g. the octahedral iron content). A UnitCellProperty object allows to define these simple mathematical relations, making the adjustment of the unit cell size automatic.

### 5.1.4. SPECIMENS, MIXTURE AND PROJECTS

Specimen objects contain all the information regarding the experimental data (the actual measurements, sample size, etc.) and the Goniometer set up (radius, slit sizes, etc.). They also have a bunch of visual settings (e.g. linwidth, line color, wether to display phase profiles separately, ...) and import/export functionality.

Maybe slightly counter-intuitive, they do not hold a direct reference to phases, but are linked with them using Mixture objects.

Mixture objects link phases and specimens together. To visualize this, in the user interface, a table is created with just as many rows as there
are Phases in the Mixture and just as many columns as there are Specimens in the Mixture. At the column headers there are slots where the user can select the Specimen and in each cell of the grid there are slots where the user can select the corresponding Phase. This allows to select different states of smectite for an AD and an EG pattern loaded in a Specimen (Figure 3), while keeping unaffected Phases, like kaolinites and micas identical.

Once a Mixture is created a number of parameters are available for automatic refinement (e.g. weight fractions from the Probability object, the average CSDS, etc.). In the refinement dialog, the user can select which parameters it would like to improve and in between which minimum and maximum values the ideal value should be searched for. A number of different refinement methods are available for this purpose.

As mentioned, Project objects group together all Mixtures, Specimens, Phases and AtomTypes and provides a way to store and (re)load these Projects.

Figure 3: screenshot showing the 'Edit Mixtures' dialog where a user can link different phases (Kaolinite, Illite, ISS RO Ca-AD, ...) with the corresponding specimen (S1AD.dat, S1EG.dat).
